

Data Summarization

Introduction to R for Public Health Researchers

Data Summarization

- Basic statistical summarization
 - `mean(x)`: takes the mean of x
 - `sd(x)`: takes the standard deviation of x
 - `median(x)`: takes the median of x
 - `quantile(x)`: displays sample quantiles of x. Default is min, IQR, max
 - `range(x)`: displays the range. Same as `c(min(x), max(x))`
 - `sum(x)`: sum of x
 - **all have a `na.rm` for missing data - discussed later**
- Transformations
 - `log` - log (base e) transformation
 - `log2` - log base 2 transform
 - `log10` - log base 10 transform
 - `sqrt` - square root

Some examples

We can use the `jhu_cars` to explore different ways of summarizing data. The `head` command displays the first 6 (default) rows of an object:

```
library(jhur)
head(jhu_cars)
```

		car	mpg	cyl	disp	hp	drat	wt	qsec	vs	am	gear	carb
1		Mazda RX4	21.0	6	160	110	3.90	2.620	16.46	0	1	4	4
2		Mazda RX4 Wag	21.0	6	160	110	3.90	2.875	17.02	0	1	4	4
3		Datsun 710	22.8	4	108	93	3.85	2.320	18.61	1	1	4	1
4		Hornet 4 Drive	21.4	6	258	110	3.08	3.215	19.44	1	0	3	1
5		Hornet Sportabout	18.7	8	360	175	3.15	3.440	17.02	0	0	3	2
6		Valiant	18.1	6	225	105	2.76	3.460	20.22	1	0	3	1

Statistical summarization

Note - the \$ references/selects columns from a `data.frame/tibble`:

```
mean(jhu_cars$hp)
```

```
[1] 146.6875
```

```
quantile(jhu_cars$hp)
```

```
0%    25%    50%    75%   100%
52.0  96.5 123.0 180.0 335.0
```

Statistical summarization

```
median(jhu_cars$wt)
```

```
[1] 3.325
```

```
quantile(jhu_cars$wt, probs = 0.6)
```

60%

3.44

Statistical summarization

`t.test` will be covered more in detail later, gives a mean and 95% CI:

```
t.test(jhu_cars$wt)
```

One Sample t-test

```
data: jhu_cars$wt
t = 18.6, df = 31, p-value < 2.2e-16
alternative hypothesis: true mean is not equal to 0
95 percent confidence interval:
 2.864478 3.570022
sample estimates:
mean of x
 3.21725
```

```
broom::tidy(t.test(jhu_cars$wt))
```

```
# A tibble: 1 x 8
  estimate statistic p.value parameter conf.low conf.high method    alternative
  <dbl>      <dbl>     <dbl>      <dbl>      <dbl>      <dbl> <chr>    <chr>
1     3.22      18.6 2.26e-18       31        2.86        3.57 One Samp... two.sided
```

Statistical summarization

Note that many of these functions have additional inputs regarding missing data, typically requiring the `na.rm` argument ("remove NAs").

```
x = c(1, 5, 7, NA, 4, 2, 8, 10, 45, 42)  
mean(x)
```

```
[1] NA
```

```
mean(x, na.rm = TRUE)
```

```
[1] 13.77778
```

```
quantile(x, na.rm = TRUE)
```

	0%	25%	50%	75%	100%
1	1	4	7	10	45

Data Summarization on matrices/data frames

- Basic statistical summarization
 - `rowMeans(x)`: takes the means of each row of x
 - `colMeans(x)`: takes the means of each column of x
 - `rowSums(x)`: takes the sum of each row of x
 - `colSums(x)`: takes the sum of each column of x
 - `summary(x)`: for data frames, displays the quantile information
- The `matrixStats` package has additional `row*` and `col*` functions
 - Like `rowSds`, `colQuantiles`

Lab Part 1

[Website](#)

TB Incidence

Please download the TB incidence data:

http://johnmuschelli.com/intro_to_r/data/tb_incidence.xlsx

Here we will read in a tibble of values from TB incidence:

```
library(readxl)
# tb <- read_excel("http://johnmuschelli.com/intro_to_r/data/tb_incidence.xlsx")
tb = jhur::read_tb()
colnames(tb)
```

```
[1] "TB incidence, all forms (per 100 000 population per year)"
[2] "1990"
[3] "1991"
[4] "1992"
[5] "1993"
[6] "1994"
[7] "1995"
[8] "1996"
[9] "1997"
[10] "1998"
[11] "1999"
[12] "2000"
[13] "2001"
[14] "2002"
[15] "2003"
[16] "2004"
[17] "2005"
```

Indicator of TB

We can rename the first column to be the country measured using the `rename` function in `dplyr` (we have to use the ` things because there are spaces in the name):

```
library(dplyr)
tb = tb %>% rename(country = `TB incidence, all forms (per 100 000 population`)
```

`colnames` will show us the column names and show that country is renamed:

```
colnames(tb)
```

```
[1] "country"  "1990"      "1991"      "1992"      "1993"      "1994"      "1995"
[8] "1996"      "1997"      "1998"      "1999"      "2000"      "2001"      "2002"
[15] "2003"      "2004"      "2005"      "2006"      "2007"
```

Summarize the data: **dplyr summarize** function

`dplyr::summarize` will allow you to summarize data. Format is `new = SUMMARY`. If you don't set a new name, it will be a messy output:

```
tb %>%
  summarize(mean_2006 = mean(`2006`, na.rm = TRUE),
            median_2007 = median(`2007`, na.rm = TRUE),
            median(`2004`, na.rm = TRUE))
```

```
# A tibble: 1 x 3
  mean_2006 median_2007 `median(\`2004\`, na.rm = TRUE)`
  <dbl>       <dbl>                      <dbl>
1     135.        53                      56
```

Column and Row means

`colMeans` and `rowMeans` must work on **all numeric data**. We will subset years before 2000 (starting with 1):

```
avgs = select(tb, starts_with("1"))
colMeans(avgs, na.rm = TRUE)
```

```
1990      1991      1992      1993      1994      1995      1996      1997
105.5797 107.6715 108.3140 110.3188 111.9662 114.1981 115.3527 118.8792
  1998      1999
121.5169 125.0435
```

```
tb$before_2000_avg = rowMeans(avgs, na.rm = TRUE)
head(tb[, c("country", "before_2000_avg")])
```

```
# A tibble: 6 x 2
  country      before_2000_avg
  <chr>          <dbl>
1 Afghanistan    168
2 Albania        26.3
3 Algeria         41.8
4 American Samoa   8.5
5 Andorra         28.8
6 Angola          225.
```

Summarize the data: `dplyr summarize` function

`dplyr::summarize` will allow you to summarize data. If you would like to summarize **all** columns, you can use `summarize_all` and pass in a function (with other arguments):

```
summarize_all(DATASET, FUNCTION, OTHER_FUNCTION_ARGUMENTS) # how to use  
  
summarize_all(avgs, mean, na.rm = TRUE)  
  
# A tibble: 1 x 10  
#> `1990` `1991` `1992` `1993` `1994` `1995` `1996` `1997` `1998` `1999`  
#> <dbl>  
1 106. 108. 108. 110. 112. 114. 115. 119. 122. 125.
```

Summary Function

Using `summary` can give you rough snapshots of each column, but you would likely use `mean`, `min`, `max`, and `quantile` when necessary (and number of NAs):

```
summary(tb)
```

country	1990	1991	1992	
Length:208	Min. : 0.0	Min. : 4.0	Min. : 2.0	
Class :character	1st Qu.: 27.5	1st Qu.: 27.0	1st Qu.: 27.0	
Mode :character	Median : 60.0	Median : 58.0	Median : 56.0	
	Mean :105.6	Mean :107.7	Mean :108.3	
	3rd Qu.:165.0	3rd Qu.:171.0	3rd Qu.:171.5	
	Max. :585.0	Max. :594.0	Max. :606.0	
	NA's :1	NA's :1	NA's :1

NA's :1	NA's :1	NA's :1	NA's :1	

Youth Tobacco Survey

Here we will be using the Youth Tobacco Survey data:

http://johnmuschelli.com/intro_to_r/data/Youth_Tobacco_Survey_YTS_Data.csv.

```
yts = jhur::read_yts()  
head(yts)
```

```
# A tibble: 6 x 31  
# ... with 24 more variables: Response <chr>, Data_Value_Unit <chr>,  
#   Data_Value_Type <chr>, Data_Value <dbl>, Data_Value_Footnote_Symbol <chr>,  
#   Data_Value_Footnote <chr>, Data_Value_Std_Err <dbl>,  
#   Low_Confidence_Limit <dbl>, High_Confidence_Limit <dbl>, Sample_Size <dbl>,  
#   Gender <chr>, Race <chr>, Age <chr>, Education <chr>, GeoLocation <chr>,  
#   TopicTypeID <chr>, TopicID <chr>, MeasureID <chr>, StratificationID1 <chr>,  
#   StratificationID2 <chr>, StratificationID3 <chr>, StratificationID4 <chr>,  
#   SubMeasureID <chr>, DisplayOrder <dbl>
```

Length and unique

unique (x) will return the unique elements of x

```
head(unique(yts$LocationDesc), 10)
```

```
[1] "Arizona"                  "Connecticut"  
[3] "Georgia"                 "Hawaii"  
[5] "Illinois"                "Louisiana"  
[7] "Mississippi"             "Utah"  
[9] "Missouri"                "National (States and DC)"
```

length will tell you the length of a vector. Combined with unique, tells you the number of unique elements:

```
length(unique(yts$LocationDesc))
```

```
[1] 50
```

Table

`table(x)` will return a frequency table of unique elements of `x`

```
head(table(yts$LocationDesc))
```

Alabama	Arizona	Arkansas	California	Colorado	Connecticut
378	240	210	96	48	384

dplyr::count

```
yts %>% count(LocationDesc)
```

```
# A tibble: 50 x 2
  LocationDesc      n
  <chr>            <int>
1 Alabama           378
2 Arizona           240
3 Arkansas          210
4 California        96
5 Colorado          48
6 Connecticut       384
7 Delaware          312
8 District of Columbia  48
9 Florida           96
10 Georgia          282
# ... with 40 more rows
```

dplyr::count

```
yts %>% count(LocationDesc, Age)
```

```
# A tibble: 50 x 3
  LocationDesc      Age       n
  <chr>        <chr>     <int>
1 Alabama    All Ages     378
2 Arizona   All Ages     240
3 Arkansas  All Ages     210
4 California All Ages      96
5 Colorado   All Ages      48
6 Connecticut All Ages    384
7 Delaware   All Ages    312
8 District of Columbia All Ages      48
9 Florida    All Ages      96
10 Georgia   All Ages    282
# ... with 40 more rows
```

Subsetting to specific columns

Let's just take smoking status measures for all genders in middle school current smoking using `filter`, and the columns that represent the year, state and percentage using `select`:

```
library(dplyr)
sub_yts = filter(yts, MeasureDesc == "Smoking Status",
                  Gender == "Overall", Response == "Current",
                  Education == "Middle School")
sub_yts = select(sub_yts, YEAR, LocationDesc, Data_Value, Data_Value_Unit)
head(sub_yts, 4)
```

```
# A tibble: 4 x 4
  YEAR LocationDesc Data_Value Data_Value_Unit
  <dbl> <chr>          <dbl> <chr>
1 2015 Arizona        3.2   %
2 2015 Connecticut    0.8   %
3 2015 Hawaii          3     %
4 2015 Illinois        2     %
```

Perform Operations By Groups: dplyr

group_by allows you group the data set by grouping variables:

```
sub_yts = group_by(sub_yts, YEAR)
head(sub_yts)
```

```
# A tibble: 6 x 4
# Groups:   YEAR [1]
  YEAR LocationDesc Data_Value Data_Value_Unit
  <dbl> <chr>        <dbl> <chr>
1 2015 Arizona       3.2  %
2 2015 Connecticut   0.8  %
3 2015 Hawaii         3    %
4 2015 Illinois       2    %
5 2015 Louisiana      5.2  %
6 2015 Mississippi    4.7  %
```

- doesn't change the data in any way, but how **functions operate on it**

Summarize the data

It's grouped!

```
sub_yts %>% summarize(year_avg = mean(Data_Value, na.rm = TRUE))
```

```
# A tibble: 17 x 2
  YEAR year_avg
  <dbl>    <dbl>
1 1999     14.6
2 2000     12.5
3 2001      9.84
4 2002      9.60
5 2003      7.49
6 2004      8.2 
7 2005      7.27
8 2006      7.37
9 2007      6.68
10 2008      5.95
11 2009      5.84
12 2010      5.6 
13 2011      5.15
14 2012      4.72
15 2013      3.76
16 2014      2.93
17 2015      2.86
```

Using the pipe

Pipe sub_yts into group_by, then pipe that into summarize:

```
yts_avgs = sub_yts %>%
  group_by(YEAR) %>%
  summarize(year_avg = mean(Data_Value, na.rm = TRUE),
            year_median = median(Data_Value, na.rm = TRUE))
head(yts_avgs)
```

```
# A tibble: 6 x 3
  YEAR year_avg year_median
  <dbl>    <dbl>      <dbl>
1 1999     14.6      14.4
2 2000     12.5       12
3 2001     9.84      9.3
4 2002     9.60      8.7
5 2003     7.49       7
6 2004     8.2       8.55
```

Ungroup the data

You usually want to perform operations on groups and may want to redefine the groups. The `ungroup` function will allow you to clear the groups from the data:

```
sub_yts = ungroup(sub_yts)  
sub_yts
```

```
# A tibble: 222 x 4  
  YEAR LocationDesc    Data_Value Data_Value_Unit  
  <dbl> <chr>          <dbl> <chr>  
1 2015 Arizona         3.2   %  
2 2015 Connecticut     0.8   %  
3 2015 Hawaii          3      %  
4 2015 Illinois         2      %  
5 2015 Louisiana        5.2   %  
6 2015 Mississippi      4.7   %  
7 2015 Missouri         2.4   %  
8 2015 New Jersey       1.2   %  
9 2015 North Carolina   2.3   %  
10 2015 North Dakota    3.6   %  
# ... with 212 more rows
```

group_by with **mutate** - just add data

We can also use `mutate` to calculate the mean value for each year and add it as a column:

```
sub_yts %>%
  group_by(YEAR) %>%
  mutate(year_avg = mean(Data_Value, na.rm = TRUE)) %>%
  arrange(LocationDesc, YEAR) # look at year 2000 value
```

```
# A tibble: 222 x 5
# Groups:   YEAR [17]
  YEAR LocationDesc Data_Value Data_Value_Unit year_avg
  <dbl> <chr>        <dbl> <chr>          <dbl>
1 2000 Alabama       19.1 %           12.5
2 2002 Alabama       15.6 %           9.60
3 2004 Alabama       13.1 %           8.2
4 2006 Alabama       13    %           7.37
5 2008 Alabama       8.7  %           5.95
6 2010 Alabama       7    %           5.6
7 2012 Alabama       7.5  %           4.72
8 2014 Alabama       6.4  %           2.93
9 2000 Arizona        11.4 %           12.5
10 2003 Arizona       8.7  %           7.49
# ... with 212 more rows
```

Counting

Standard statistics can be calculated. There are other functions, such as `n()` count the number of observations.

```
sub_yts %>%
  group_by(YEAR) %>%
  summarize(n = n(),
            mean = mean(Data_Value, na.rm = TRUE)) %>%
  head
```

```
# A tibble: 6 x 3
  YEAR     n   mean
  <dbl> <int> <dbl>
1 1999     10 14.6
2 2000     27 12.5
3 2001     11  9.84
4 2002     23  9.60
5 2003     12  7.49
6 2004     14  8.2
```

Lab Part 2

[Website](#)

Data Summarization/Visualization: ggplot2

ggplot2 is a package of plotting that is very popular and powerful (using the grammar of graphics). We will use qplot ("quick plot") for most of the basic examples:

```
qplot
```

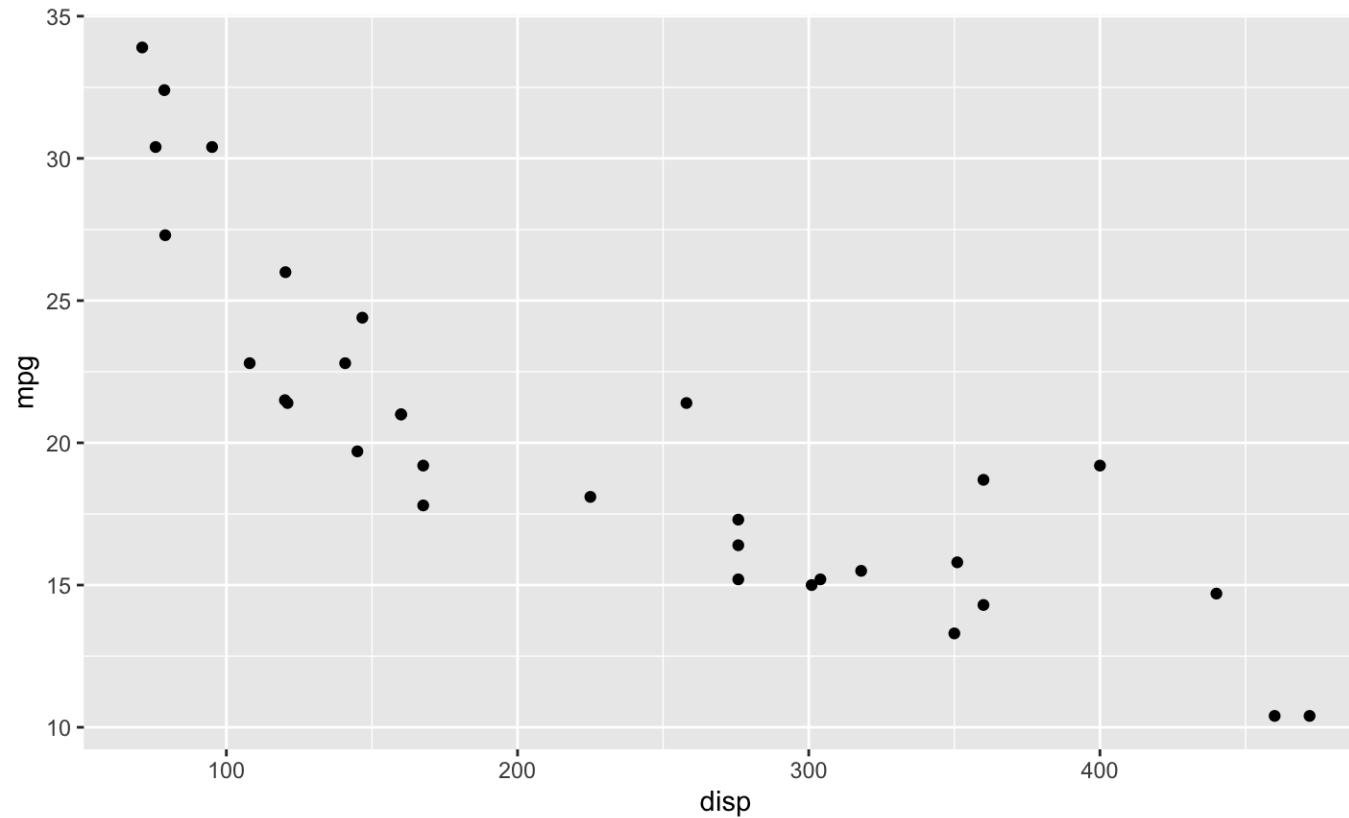

```
function (x, y, ..., data, facets = NULL, margins = FALSE, geom = "auto",
         xlim = c(NA, NA), ylim = c(NA, NA), log = "", main = NULL,
         xlab = NULL, ylab = NULL, asp = NA, stat = NULL, position = NULL)
NULL
```

Basic Plots

Plotting is an important component of exploratory data analysis. We will review some of the more useful and informative plots here. We will go over formatting and making plots look nicer in additional lectures.

Scatterplot

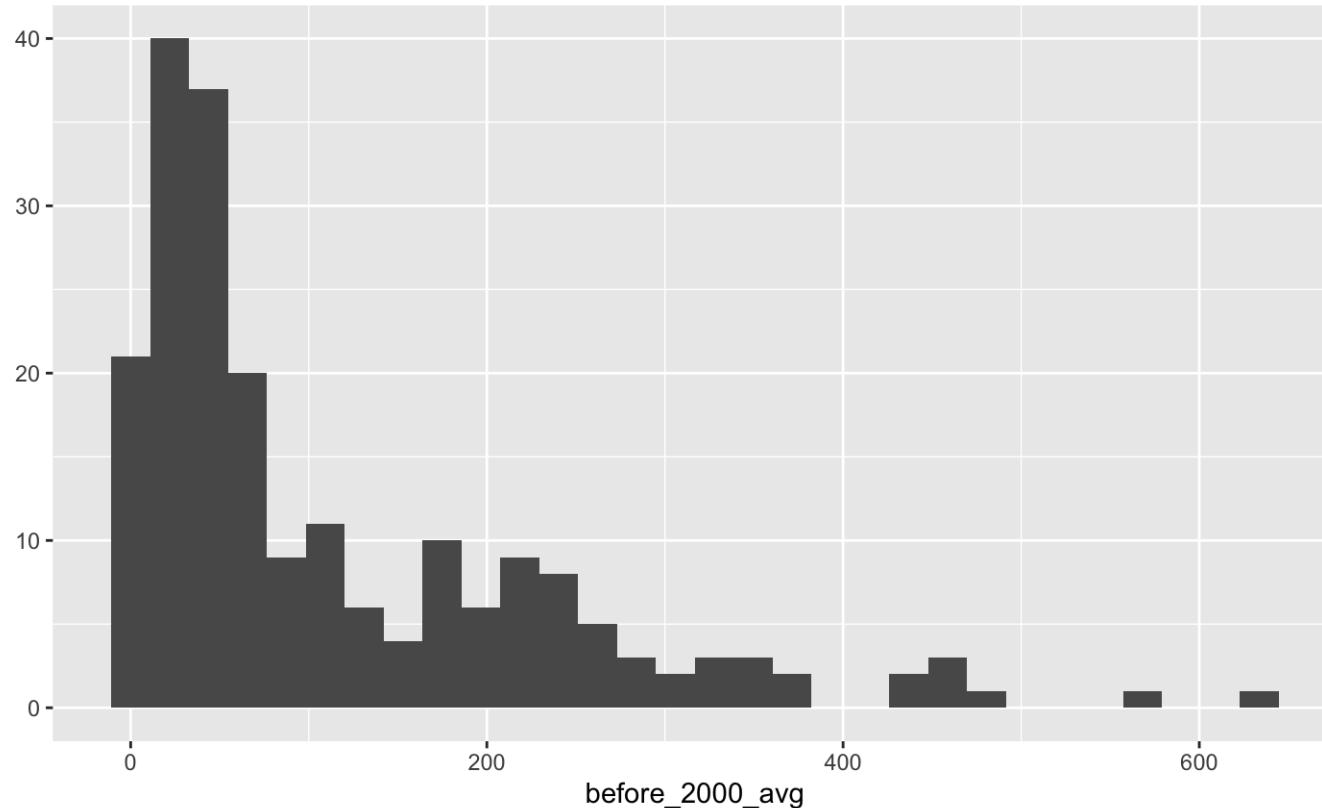

```
library(ggplot2)
qplot(x = disp, y = mpg, data = jhu_cars)
```

Histograms

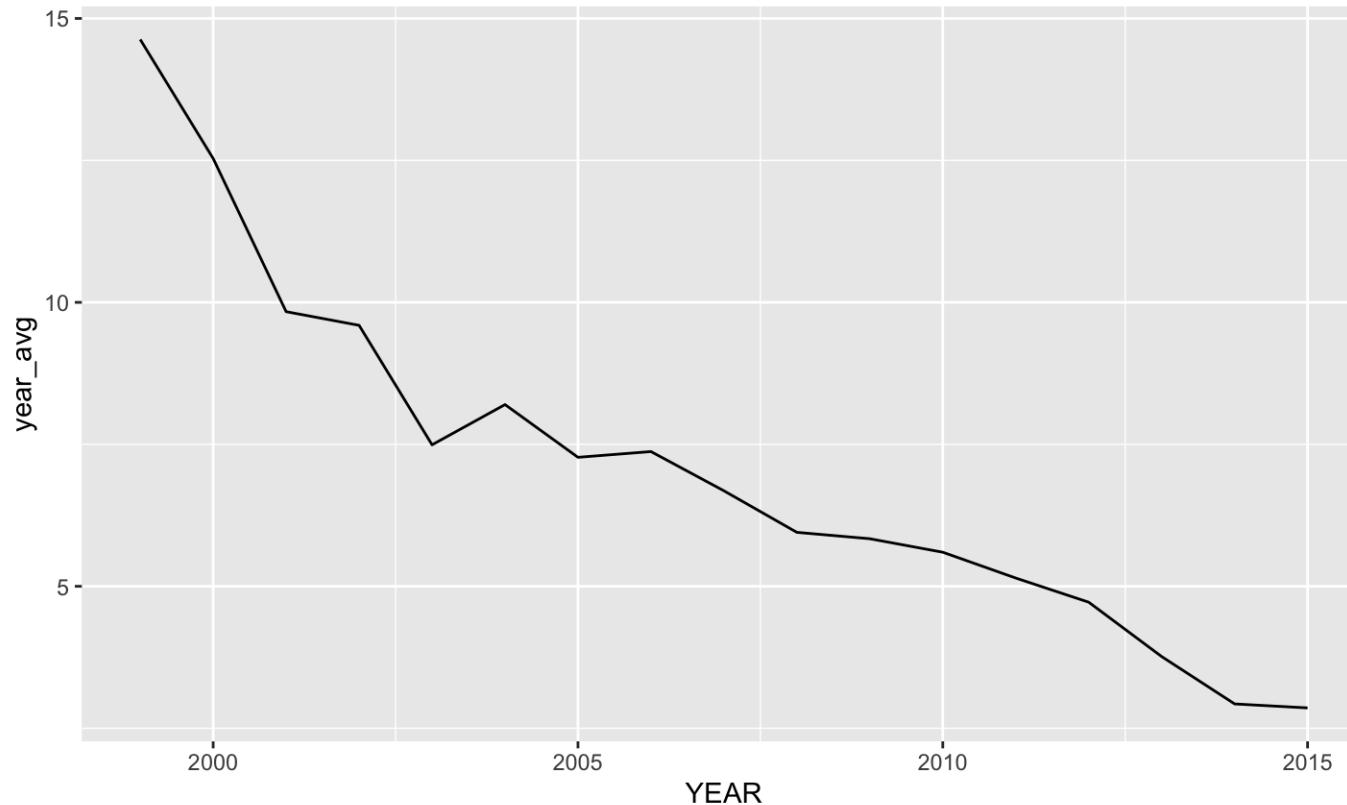

```
qplot(x = before_2000_avg, data = tb, geom = "histogram")
```

Warning: Removed 1 rows containing non-finite values (stat_bin).

Plot with a line

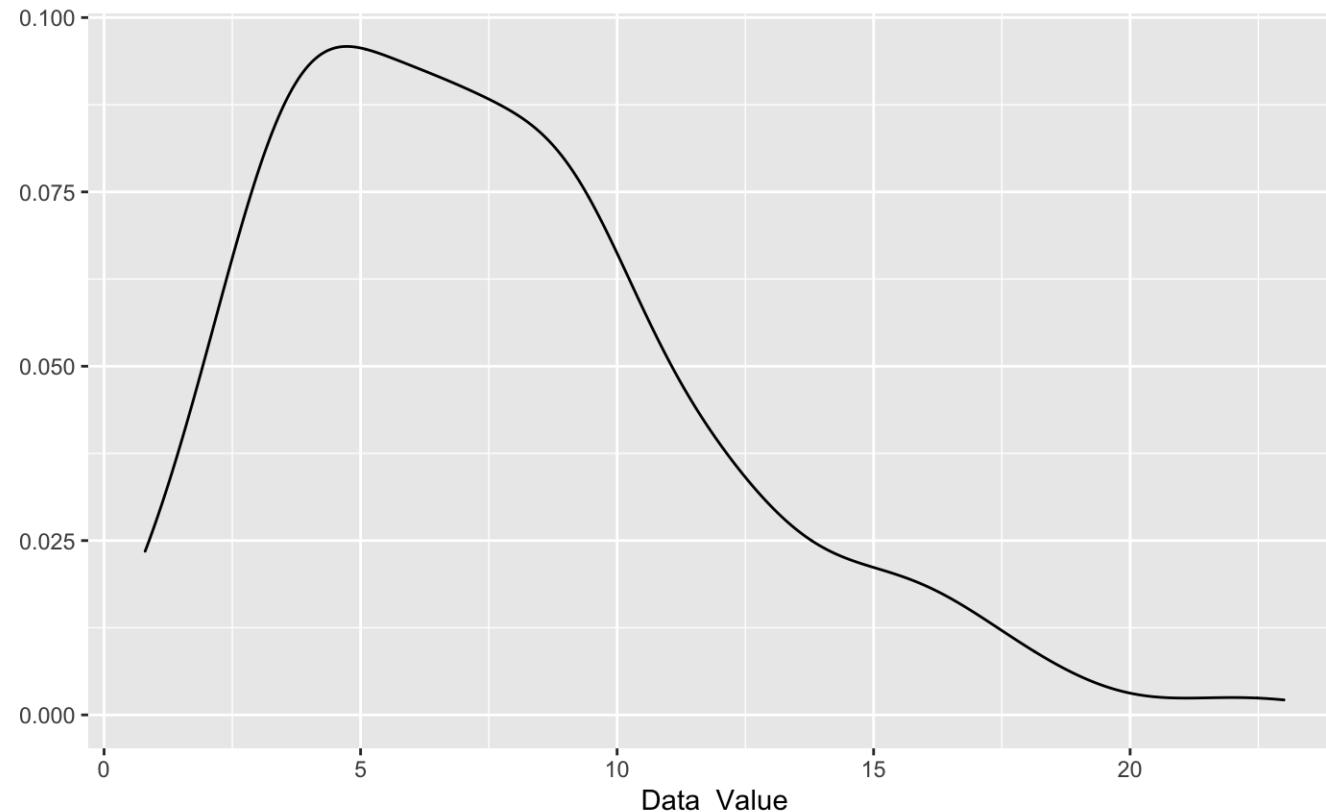

```
qplot(x = YEAR, y = year_avg, data = yts_avgs, geom = "line")
```

Density

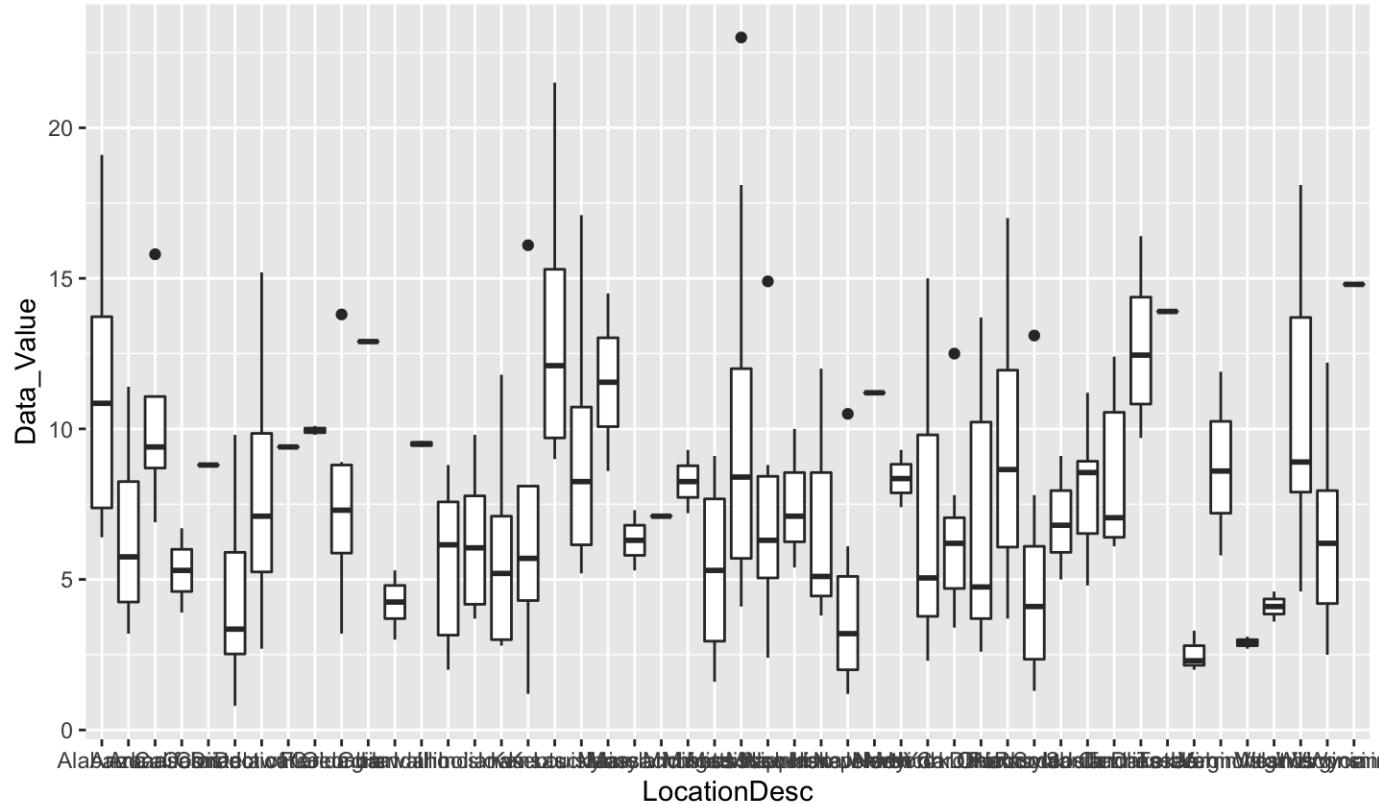

Over all years and states, this is the density of smoking status incidence:

```
qplot(x = Data_Value, data = sub_yts, geom = "density")
```

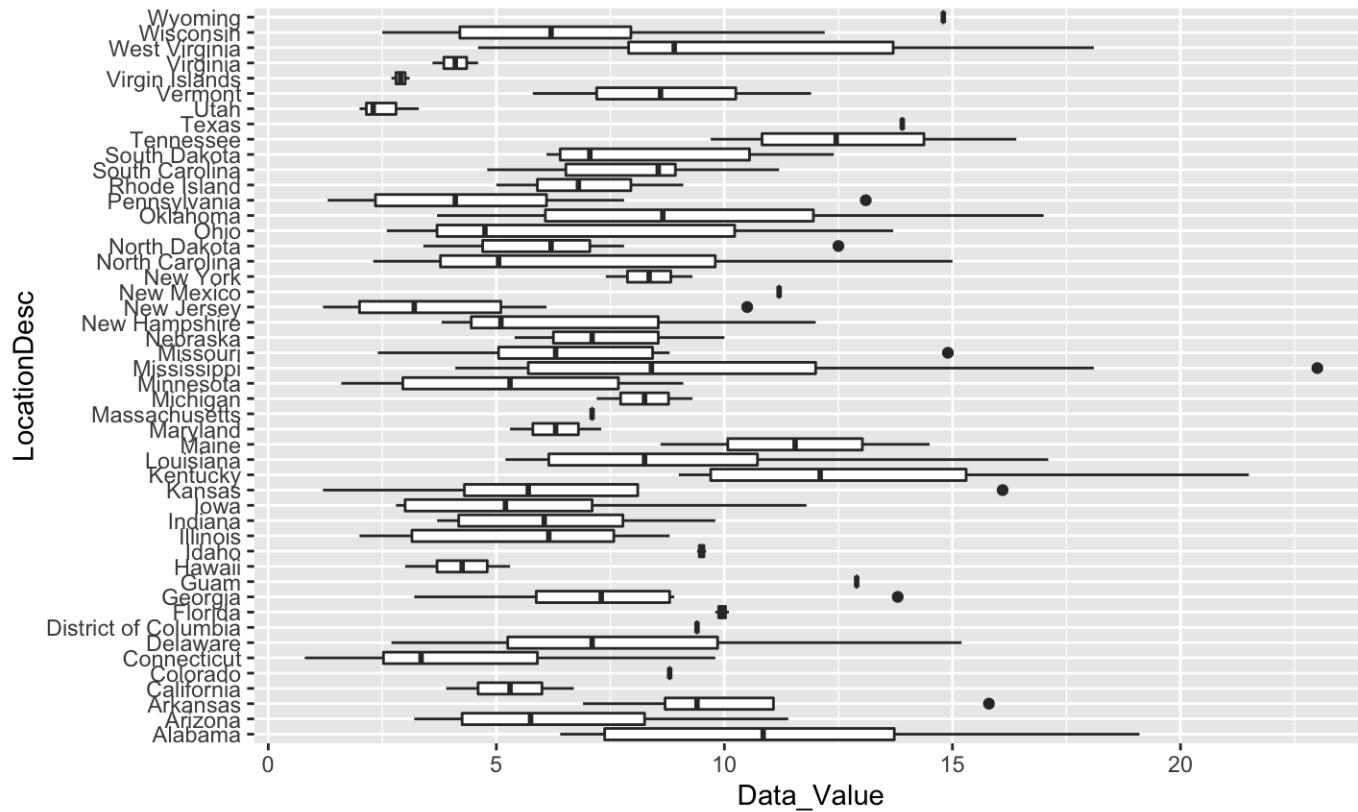

Boxplots

```
qplot(x = LocationDesc, y = Data_Value, data = sub_yts, geom = "boxplot")
```

Boxplots

```
qplot(x = LocationDesc, y = Data_Value,  
      data = sub_yts, geom = "boxplot") + coord_flip()
```

Lab Part 3

[Website](#)

Base functions for plotting

- Basic summarization plots:
 - `plot(x, y)`: scatterplot of x and y
 - `boxplot(y~x)`: boxplot of y against levels of x
 - `hist(x)`: histogram of x
 - `density(x)`: kernel density plot of x

Conclusion

- `group_by` is very powerful, especially with `summarise/summarize`
- Using `group_by` and `mutate` keeps all the rows and repeats a value, `summarize` reduces the number of rows
- The `matrixStats` package extends this to `colMedians`, `colMaxs`, etc.

Base R Plots - not covered

Basic Plots

Plotting is an important component of exploratory data analysis. We will review some of the more useful and informative plots here. We will go over formatting and making plots look nicer in additional lectures.

Scatterplot

```
plot(jhu_cars$mpg, jhu_cars$disp)
```

Histograms

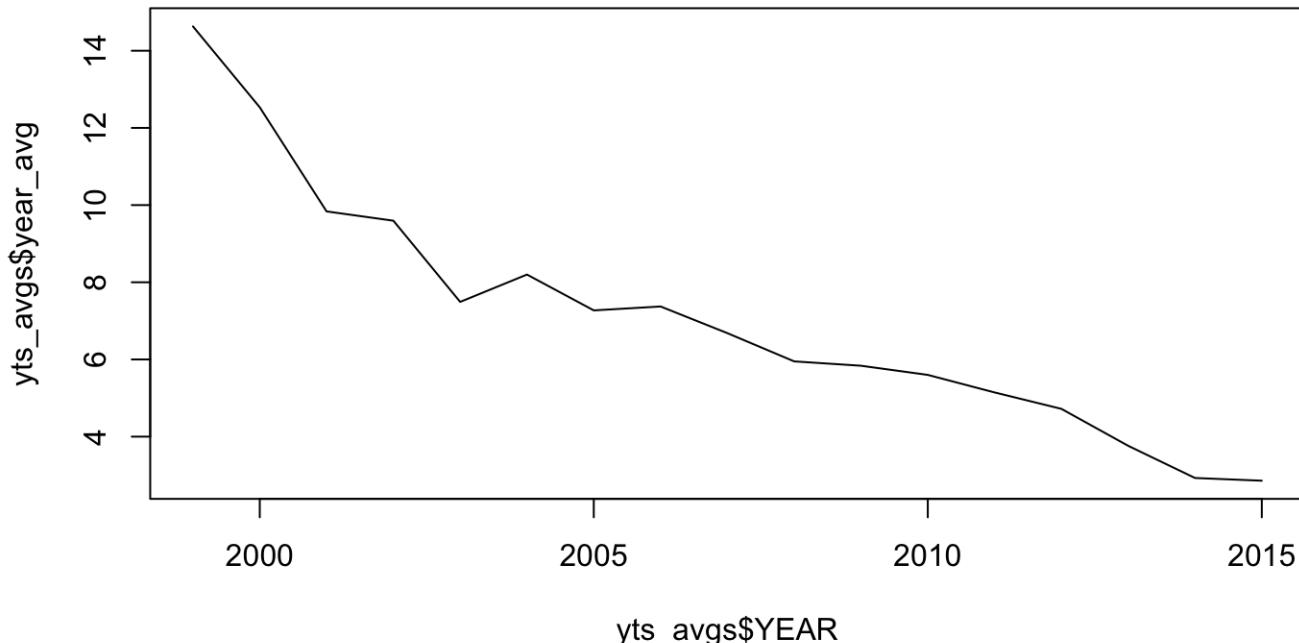

```
hist(tb$before_2000_avg)
```

Plot with a line

type = "l" means a line

```
plot(yts_avgs$YEAR, yts_avgs$year_avg, type = "l")
```

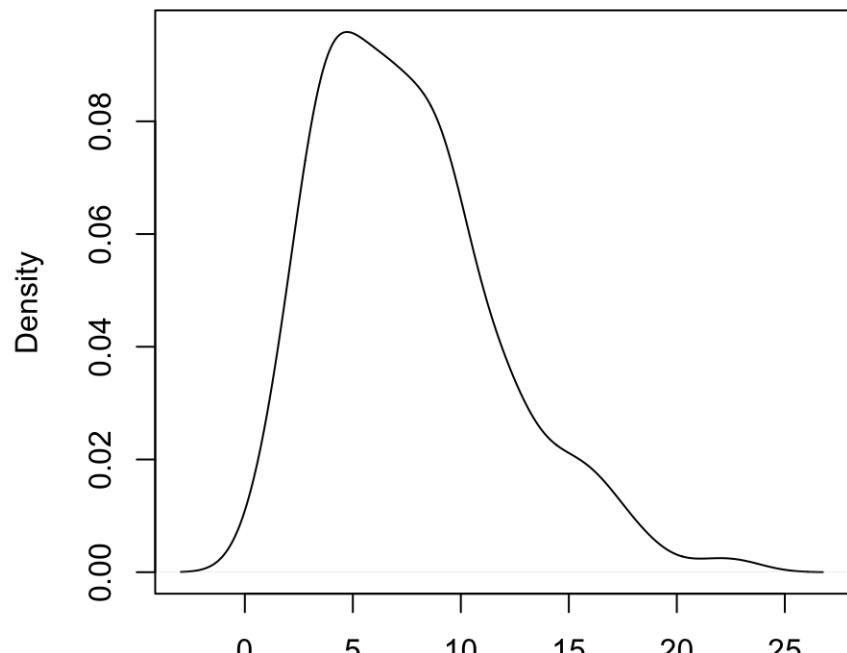

Density

Over all years and states, this is the density of smoking status incidence:

```
plot(density(sub_yts$Data_Value))
```

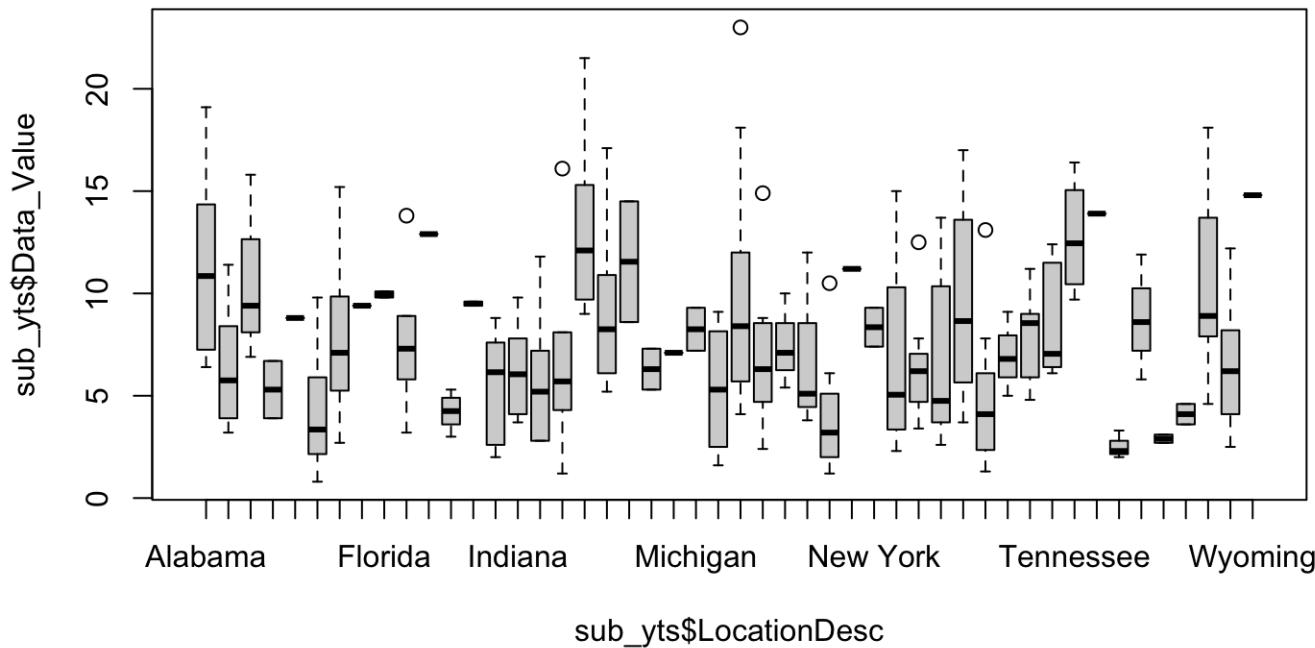

```
density.default(x = sub_yts$Data_Value)
```

N = 222 Bandwidth = 1.254

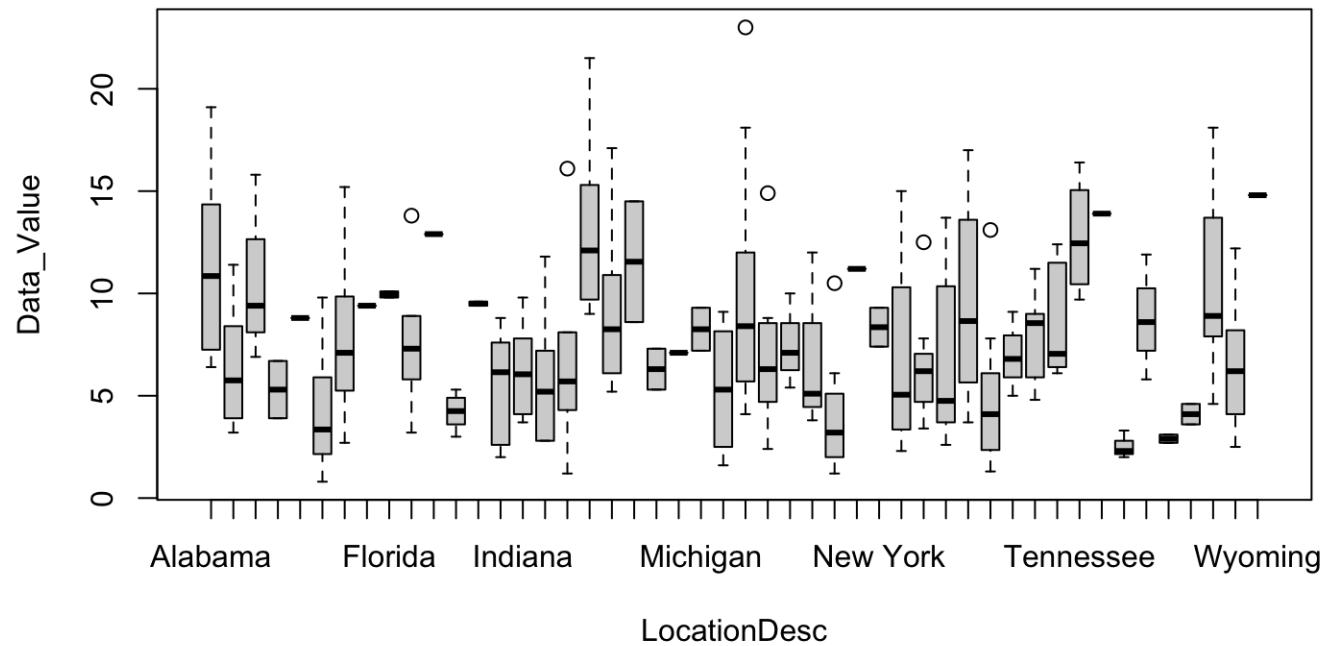

Boxplots

```
boxplot(sub_yts$Data_Value ~ sub_yts$LocationDesc)
```

Boxplots

```
boxplot(Data_Value ~ LocationDesc, data = sub_yts)
```

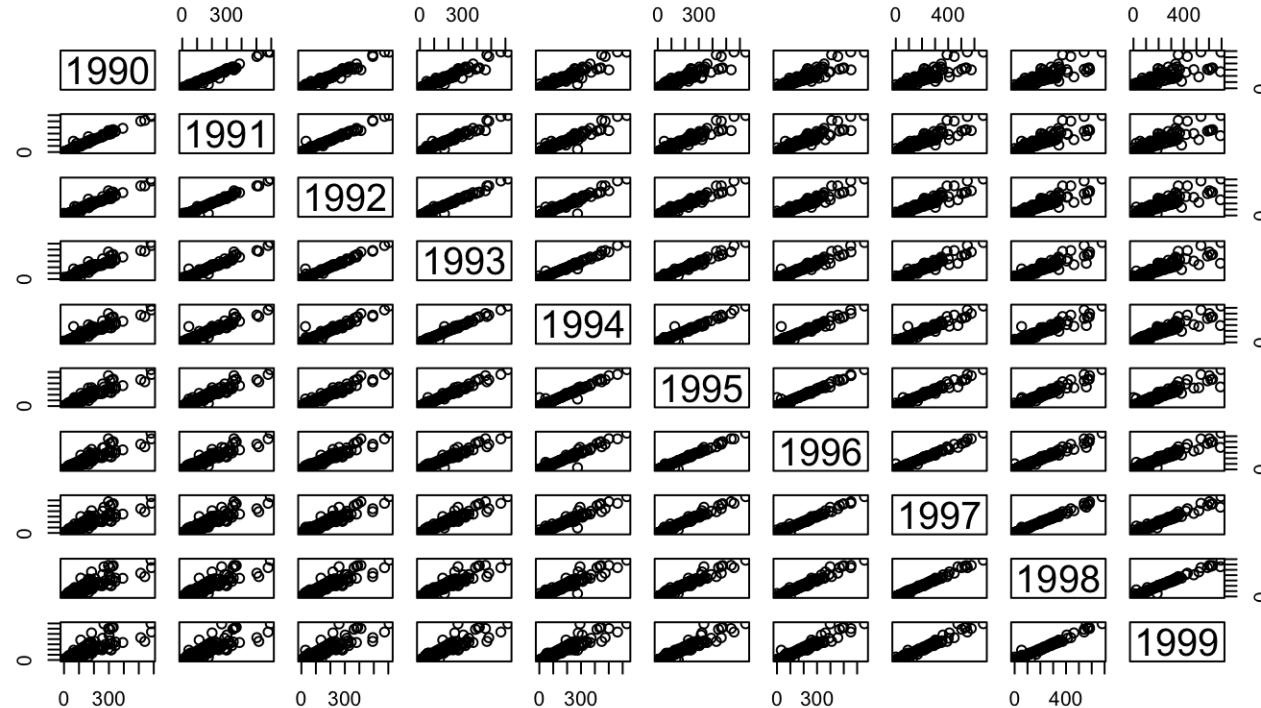

Data Summarization for `data.frames`

- Basic summarization plots
 - `matplot(x, y)`: scatterplot of two matrices, x and y
 - `pairs(x, y)`: plots pairwise scatter plots of matrices x and y, column by column

Matrix plot

pairs (avgs)

Apply statements

You can apply more general functions to the rows or columns of a matrix or data frame, beyond the mean and sum.

`apply(X, MARGIN, FUN, ...)`

X : an array, including a matrix.

MARGIN : a vector giving the subscripts which the function will be applied over. E.g., for a matrix 1 indicates rows, 2 indicates columns, c(1, 2) indicates rows and columns. Where X has named dimnames, it can be a character vector selecting dimension names.

FUN : the function to be applied: see ‘Details’.

... : optional arguments to FUN.

Apply statements

```
apply(avgs, 2, mean, na.rm=TRUE) # column means
```

```
1990      1991      1992      1993      1994      1995      1996      1997  
105.5797 107.6715 108.3140 110.3188 111.9662 114.1981 115.3527 118.8792  
1998      1999  
121.5169 125.0435
```

```
head(apply(avgs, 1, mean, na.rm=TRUE)) # row means
```

```
[1] 168.0 26.3 41.8 8.5 28.8 224.6
```

```
apply(avgs, 2, sd, na.rm=TRUE) # columns sds
```

```
1990      1991      1992      1993      1994      1995      1996      1997  
110.6440 112.7687 114.4853 116.6744 120.0931 122.7119 126.1800 131.0858  
1998      1999  
137.3754 146.0755
```

```
apply(avgs, 2, max, na.rm=TRUE) # column maxs
```

```
1990 1991 1992 1993 1994 1995 1996 1997 1998 1999  
585  594  606  618  630  642  655  668  681  695
```

Other Apply Statements

- `tapply()`: 'grouping' apply
- `lapply()`: 'list' apply [tomorrow]
- `sapply()`: 'simple' apply [tomorrow]
- Other less used ones...

See more details here: <http://nsaunders.wordpress.com/2010/08/20/a-brief-introduction-to-apply-in-r/>

- Commonly used, but we will discuss how to do all steps in `dplyr`
